

Smalltalk Programming

1 Introduction

In this programming assignment, you will implement a number of classes and methods in μ Smalltalk in order to gain familiarity with the language and to practice object-oriented programming.

Download `prog06.smt`, `prog06_tests.smt`, and `prog06_tests.soln.out` (or copy from `/usr/local/pub/mtf/plc/programming/prog06-smalltalk` on the CS Department Linux systems). The first is a template for your submission and also includes a number of supporting classes. The second is a test suite for the assignment and the third is reference solution's output on the test suite.

2 Description

This assignment investigates writing μ Smalltalk classes that represent immutable, space-efficient vectors, which we call “xvectors”. Complete the definitions of the abstract class `XVector` and its concrete sub-classes `ArrayXVector`, `ConcatXVector`, `RepeatXVector`, `ReverseXVector`, `SwizzleXVector`, and `BlockXVector` to provide the protocols specified in Figures 1, 2, and 3. (Note: These classes represent *space-efficient* vectors. Hence, they should not unnecessarily allocate new data. The trade-off is that the `at:` method on xvectors is typically not $O(1)$.)

See Requirements and Submissions for important restrictions.

XVector instance protocol

<i>display methods</i>	
<code>print</code>	Print the receiver on standard output; an xvector is printed as <<, a space character, the elements of the receiver separated by spaces, a space character, and >>.
<code>debug</code>	Print a representation of the xvector on standard output; the representation is constructed from the name of the receiver's class, an open parenthesis, the arguments used to construct the receiver (separated by commas), and a close parenthesis; any xvector arguments used to construct the receiver are printed using <code>debug</code> ; non-xvector arguments used to construct the receiver are printed using <code>print</code> . (subclass responsibility) (10pts) Note: The initial basis of the μ Smalltalk interpreter includes global variables <code>newline</code> , <code>space</code> , <code>semicolon</code> , <code>quotemark</code> , <code>left-round</code> , <code>right-round</code> , <code>left-square</code> , <code>right-square</code> , <code>left-curly</code> , and <code>right-curly</code> , which are bound to objects of class <code>Char</code> that represent the new line character, the space character, the semicolon character ";", the quote character "'", the left parenthesis character "(", the right parenthesis character ")", the left square bracket character "[", the right square bracket character "]", the left curly brace character "{", and the right curly brace character "}". Such characters are useful for printing (send them the <code>print</code> message), but cannot be expressed using μ Smalltalk's literal symbol notation.
<i>observer methods</i>	
<code>isEmpty</code>	Answer whether the receiver has any elements. (like the corresponding <code>Collection</code> method)
<code>size</code>	Answer how many elements the receiver has. (like the corresponding <code>Collection</code> method) (subclass responsibility) (10pts)
<code>at: anIndex</code>	Answer the element at position <code>anIndex</code> , or report the error <code>index-out-of-bounds</code> if the position <code>anIndex</code> is out of bounds. A non-negative position counts forward from the start of the xvector (i.e., (<code>xvector at: 0</code>) answers the first element); a negative position counts backward from the end of the xvector (i.e., (<code>xvector at: -1</code>) answers the last element).
<code>at:ifAbsent: anIndex exnBlock</code>	Answer the element at position <code>anIndex</code> or the result of evaluating <code>exnBlock</code> if the position <code>anIndex</code> is out of bounds. (see <code>at:</code> method comments) (10pts)
<code>includes: anObject</code>	Answer whether the receiver has <code>anObject</code> ; uses <code>=</code> to compare <code>anObject</code> to elements. (like the corresponding <code>Collection</code> method)
<code>occurrencesOf: anObject</code>	Answer how many of the receiver's elements are equal to <code>anObject</code> ; uses <code>=</code> to compare <code>anObject</code> to elements. (like the corresponding <code>Collection</code> method)
<code>detect: aBlock</code>	Answer the first element <code>x</code> in the receiver for which (<code>aBlock value: x</code>) is true, or report the error <code>no-object-detected</code> if none. (like the corresponding <code>Collection</code> method)
<code>detect:ifNone: aBlock exnBlock</code>	Answer the first element <code>x</code> in the receiver for which (<code>aBlock value: x</code>) is true or answer (<code>exnBlock value</code>) if none.
<code>sum</code>	Answer the sum of the elements in the receiver; assumes all elements are members of the same <code>Number</code> subclass and answers an <code>Integer</code> if the receiver is empty. (5pts)
<code>product</code>	Answer the product of the elements in the receiver; assumes all elements are members of the same <code>Number</code> subclass and answers an <code>Integer</code> if the receiver is empty. (5pts)
<code>min</code>	Answer the minimum element in the receiver or report the error <code>min-of-empty</code> if the receiver is empty; assumes all elements are members of the same <code>Magnitude</code> subclass. (5pts)
<code>max</code>	Answer the maximum element in the receiver or report the error <code>max-of-empty</code> if the receiver is empty; assumes all elements are members of the same <code>Magnitude</code> subclass. (5pts)

Figure 1: XVector instance protocol

XVector instance protocol (continued)

<i>iterator methods</i>	
<code>do: aBlock</code>	For each element <code>x</code> of the receiver (in order of increasing position), evaluate (<code>aBlock value: x</code>). (like the corresponding <code>Collection</code> method) (10pts)
<code>inject:into: aValue binaryBlock</code>	Evaluates <code>binaryBlock</code> once for each element in the receiver. The first argument of the block is an element from the receiver; the second argument is the result of the previous evaluation of the block, starting with <code>aValue</code> . Answer the final value of the block. (like the corresponding <code>Collection</code> method)
<i>comparison methods</i>	
<code>= anObject</code>	Answers whether the receiver is equal to <code>anObject</code> ; an <code>xvector</code> is not equal to an object that is not an instance of <code>XVector</code> and two <code>xvectors</code> are equal if they have the same size and elements of corresponding positions are equal. (like the corresponding <code>Collection</code> method) (10pts)
<code>< anXVector</code>	Answers whether the receiver is less than the argument; <code>xvectors</code> are compared via lexicographic order; assumes all elements are members of the same <code>Magnitude</code> subclass. (like the corresponding <code>Magnitude</code> method) (10pts)
<code>> anXVector</code>	Answers whether the receiver is greater than the argument. (see <code><</code> method comments; like the corresponding <code>Magnitude</code> method)
<code><= anXVector</code>	Answers whether the receiver is no greater than the argument. (see <code><</code> method comments; like the corresponding <code>Magnitude</code> method)
<code>>= anXVector</code>	Answers whether the receiver is no less than the argument. (see <code><</code> method comments; like the corresponding <code>Magnitude</code> method)
<code>min: anXVector</code>	Answer the lesser of the receiver and <code>anXVector</code> . (see <code><</code> method comments; like the corresponding <code>Magnitude</code> method)
<code>max: anXVector</code>	Answer the greater of the receiver and <code>anXVector</code> . (see <code><</code> method comments; like the corresponding <code>Magnitude</code> method)
<i>producer methods</i>	
<code>+ anXVector</code>	Answer an <code>xvector</code> that represents the concatenation of the receiver and <code>anXVector</code> .
<code>* anInteger</code>	If <code>anInteger</code> is non-negative, answer an <code>xvector</code> that represents <code>anInteger</code> concatenations of the receiver. If <code>anInteger</code> is negative, report the error <code>negative-repeat</code> . (There may be opportunities to override this method in a subclass; explain your reasoning in a comment at the overriding method implementation. Note: Remember that these classes represent <i>space-efficient</i> vectors. An overriding implementation should not allocate more data than the generic superclass implementation and should make the answered <code>xvector</code> more efficient for (some) operations than the <code>xvector</code> answered by the generic superclass implementation. (bonus 3pts))
<code>reverse</code>	Answer an <code>xvector</code> that represents the reversal of the receiver. (There may be opportunities to override this method in a subclass; explain your reasoning in a comment at the overriding method implementation. (see <code>*</code> method comments) (bonus 3pts))
<code>fromIndex:toIndex: aStartIndex anEndIndex</code>	Answer an <code>xvector</code> that represents the elements of the receiver from position <code>aStartIndex</code> to position <code>anEndIndex</code> (inclusive). If position <code>aStartIndex</code> comes after position <code>anEndIndex</code> in the receiver, then the answered <code>xvector</code> has elements from the end of the receiver followed by elements from the start of the receiver (i.e., the slice “wraps around”). If either position <code>aStartIndex</code> or position <code>anEndIndex</code> are out of bounds, then report the error <code>index-out-of-bounds</code> . (see <code>at:</code> method comments) (10pts) (There may be opportunities to override this method in a subclass; explain your reasoning in a comment at the overriding method implementation. (see <code>*</code> method comments) (bonus 3pts))
<i>private methods (internal to XVector classes)</i>	
<code>elem: anIndex</code>	Answer the element at position <code>anIndex</code> ; assumes that the position <code>anIndex</code> is non-negative and within bounds. (subclass responsibility) (10pts)

Figure 2: `XVector` instance protocol (continued)

ArrayXVector class protocol

<code>withArr: anArray</code>	Create and answer an xvector that holds the elements of <code>anArray</code> ; since an xvector is immutable, the elements of <code>anArray</code> must be copied at the time of construction.
-------------------------------	--

ConcatXVector class protocol

<code>withXV1:withXV2: anXVector1 anXVector2</code>	Create and answer an xvector that represents the concatenation of <code>anXVector1</code> and <code>anXVector2</code> . (2pts)
---	--

RepeatXVector class protocol

<code>withXV:withN: anXVector anInteger</code>	If <code>anInteger</code> is non-negative, create and answer an xvector that represents <code>anInteger</code> concatenations of <code>anXVector</code> . If <code>anInteger</code> is negative, report the error <code>negative-repeat-count</code> . (2pts)
--	---

ReverseXVector class protocol

<code>withXV: anXVector</code>	Create and answer an xvector that represents the reversal of <code>anXVector</code> . (2pts)
--------------------------------	--

SwizzleXVector class protocol

<code>withXV1:withXV2: anXVector1 anXVector2</code>	Create and answer an xvector that represents the <i>swizzle</i> of <code>anXVector1</code> and <code>anXVector2</code> : the first element of the swizzle is the first element of <code>anXVector1</code> , the second element of the swizzle is the first element of <code>anXVector2</code> , the third element of the swizzle is the second element of <code>anXVector1</code> , the fourth element of the swizzle is the second element of <code>anXVector2</code> , and so on. If <code>anXVector1</code> and <code>anXVector2</code> are of unequal lengths, then the swizzle concludes with the excess elements from the longer one. (2pts)
---	--

BlockXVector class protocol

<code>withN:withBlock: anInteger aBlock</code>	If <code>anInteger</code> is non-negative, create and answer an xvector that is of size <code>anInteger</code> and the element at position <code>i</code> is obtained by (<code>aBlock value: i</code>). <code>aBlock</code> may assume that it will only be evaluated with indices <code>i</code> such that $0 \leq i < \text{anInteger}$. If <code>anInteger</code> is negative, report the error <code>negative-block-size</code> . (2pts)
--	--

Figure 3: XVector sub-classes class protocols

3 Requirements and Submission

Your submission must be a valid μ Smalltalk program. In particular, it must pass the following test:

```
$ cat prog06.smt | /usr/local/pub/mtf/plc/bin/usmalltalk -q > /dev/null
```

without any error messages. If your submission produces error messages (e.g., syntax errors), then your submission will not be tested and will result in zero credit for the assignment.

Submit `prog06.smt` to the **Programming 06** Dropbox on MyCourses by the due date.

4 Hints

- Remember to double-check `ifTrue:ifFalse:` message sends; the receiver must be a Boolean object and the two arguments must be (nullary) blocks.
- Remember to double-check `whileTrue:` message sends; the receiver must be a (nullary) block (that answers a Boolean object) and the argument must be a (nullary) block.
- You may (and should) add instance variables to the concrete sub-classes.
- You may define additional (private) helper methods.
- You may define additional classes.
- Note that the `do:` method is a concrete method of the `XVector` superclass. This is different from the `Collection` hierarchy, where the `do:` method is an abstract method of the `Collection` superclass.
- Note that the `sum` and `product` methods assume that all elements of the receiver are elements of the same `Number` subclass. Thus, these methods should work on `xvector`'s of `SmallInteger`, `Fraction`, and `Float`. An inelegant solution uses `isKindOf:` to dynamically determine the specific `Number` subclass. An elegant solution uses the `coerce:` method of the `Number` protocol.
- Note that the `min` and `max` methods assume that all elements of the receiver are elements of the same `Magnitude` subclass. Thus, these methods should work on `xvector`'s of `SmallInteger`, `Fraction`, and `Float`. Also, note that the methods report an error if the receiver is empty. So, the meaningful computation of the minimum or maximum element will only proceed when the receiver is non-empty.
- Note that the argument of the `=` method can be an arbitrary object. It would be appropriate to use the `isKindOf:` method to determine if the argument is an `xvector` and then proceed to comparing elements. Be sure to use `=` to compare elements, not `==`. Note that `xvectors` of different sizes are never equal.
- Note that the `<` compares the receiver and argument `xvectors` via lexicographic comparison. Lexicographic order is “dictionary order”. In particular, `<< -6 -5 -4 >>` is less than `<< 1 >>` and `<< 1 >>` is less than `<< 6 5 4 >>`.

- Note that the `fromIndex:toIndex:` method of `XVector` and the constructors for the sub-classes of `XVector` should not explicitly construct a data structure proportional in size to the created vector. This is perhaps best exemplified by the following transcript:

```

-> (val xv (ArrayXVector withArr: '(1 2 3 4 5)))
<< 1 2 3 4 5 >>
-> (val rxv1 (RepeatXVector withXV:withN: xv 9))
<< 1 2 3 4 5 1 2 3 4 5 1 2 3 4 5 1 2 3 4 5 1 2 3 4 5 1 2 3 4 5 1 2 3 4 5 1 2 3 4 5 1 2 3 4 5 >>
-> (size rxv1)
45
-> (at: rxv1 0)
1
-> (at: rxv1 4)
5
-> (at: rxv1 5)
1
-> (at: rxv1 9)
5
-> (val rxv2 nil)
nil
-> (begin (set rxv2 (RepeatXVector withXV:withN: xv 9999)) nil)
nil
-> (rxv2 size)
49995
-> (rxv2 at: 0)
1
-> (rxv2 at: 4)
5
-> (rxv2 at: 5)
1
-> (rxv2 at: 9)
5
-> (rxv2 at: 4321)
2

```

How can you efficiently compute the size of `rxv2` without explicitly constructing a 49995 element data structure, knowing that `rxv2` was constructed from `xv` and a repeat count of 9999? How can you efficiently determine the element at index 4321 of `rxv2`?

A Interpreter

A reference μ Smalltalk interpreter is available on the CS Department Linux systems (e.g., `glados.cs.rit.edu` and `queeg.cs.rit.edu` and ICLs 1 and 2) at:

```
/usr/local/pub/mtf/plc/bin/usmalltalk
```

Use the reference interpreter to check your code.

Source code for the interpreter is available on the CS Department file system at:

```
/usr/local/pub/mtf/plc/src/bare/usmalltalk
```

B Test Suite

Executing

```
$ cat prog06.smt prog06_tests.smt | /usr/local/pub/mtf/plc/bin/usmalltalk -qq > prog06_tests.out
```

will run the interpreter on the contents of the files `prog06.smt` and `prog06_tests.smt` (all tests) without prompts or responses printed and save the output to the file `prog06_tests.out`; then executing

```
$ diff prog06_tests.soln.out prog06_tests.out
```

will compare the files `prog06_tests.soln.out` and `prog06_tests.out` and print any differences.

Similarly, executing

```
$ cat prog06.smt util.smt A-at:ifAbsent:.smt | /usr/local/pub/mtf/plc/bin/usmalltalk -qq > A-at:ifAbsent:.out
```

will run the interpreter on the contents of the files `prog06.smt`, `util.smt`, and `A-at:ifAbsent:.smt` (an individual test file) without prompts or responses printed and save the output to the file `A-at:ifAbsent:.smt.out`; then executing

```
$ diff A-at:ifAbsent:.soln.out A-at:ifAbsent:.out
```

will compare the files `A-at:ifAbsent:.soln.out` and `A-at:ifAbsent:.soln.out` and print any differences.

Note: Due to the interdependencies between the classes and methods of the assignment, it is not easy to test individual pieces of functionality in isolation. You will probably find the test suite most helpful after you have a mostly completed assignment, when you can use the test suite to discover and diagnose any minor errors or missing corner cases. You will probably not find it helpful to use the test suite as the guiding force for completing the assignment.

The best suggestion is to use the system interactively to debug one method at a time.

Note: Most of the `.soln.out` files are simply `All 6 tests passed.`, but a small number include lines like `(debug cxv01) --> ConcatXVector(ArrayXVector(()),ArrayXVector(()))`, which demonstrates the behavior of the `debug` method.
